In statistics the frequency (or absolute frequency) of an event is the number of times the event occurred in an experiment or study. [1] : 12–19 These frequencies are often graphically represented in histograms .Frequency density. It gives the frequency per unit for the data in this class, where the unit is the unit of measurement of the data. This allows for a meaningful comparison of different classes where the class widths may not be equal. When drawing a histogram, the axes are the measurement and the frequency density:Frequency density = frequency ÷ class width A histogram is usually drawn when you have continuous data and the groups in the frequency table are of unequal size To draw a histogram you will need to work out the frequency density.1 Answer. Frequency density is defined as the ratio of the frequency of a class to its width. There is no proportionality constant or anything of that sort. I feel this page will help you. I am afraid the book is wrong. You can accept the answer if it helped you., Frequency Density In Statistics.
